Rectangular coordinates or Cartesian coordinates, they come in the form (x, y) . It's easy to remember that they called rectangular coordinates, because if you start at the origin and move first in the coordinate x -coordinate, and then at the y -coordinate, your path is a horizontal line, followed by a vertical line which forms two sides of a rectangle. Polar coordinates, on the other hand, come in the form (r, θ) . Instead of moving from the origin using horizontal and vertical lines, we take instead the angle θ , which is the direction, and then moving from the origin some distance r . Rectangular to Polar conversion formula: $x^2 + y^2 = r^2$; $x = r \cos \theta$; $y = r \sin \theta$. We start by connecting the x and y values from the rectangular point on the left side of $x^2 + y^2 = r^2$, and we will get a value for r . Then we connect them to $x = r \cos \theta$ and the $y = r \sin \theta$ - value and connect them to $y = r \sin \theta$. This turns out to be a solution for both equations is the value of θ . We should use in our converted polar point. Polar to rectangular conversion formula: $x = r \cos \theta$; $y = r \sin \theta$. All we have to do is take the values of r and θ from the polar point, connect them to the right sides of these conversion formulas and solve for x and y . The values we need for the equivalent rectangular coordinate point. Example: Convert the rectangular point in a polar point. $(-1, -1)$. $w\check{a}ks\check{o}cker$ connects the x and y - Values from our rectangular point in $x^2 + y^2 = r^2$ to find r . $x^2 + y^2 = r^2$; $1 + 1 = r^2$; $r = \sqrt{2}$. Note: there are multiple ways to indicate the same polar point. Even though $r = \pm \sqrt{2}$, we only use the positive solution because the negative solution will actually return the same polar point. This will always be true, so you can always walk away with just using the positive solution to r . Link: $r = \sqrt{2}$ and $x = 1$ in $x = r \cos \theta$ to find θ . We get $x = r \cos \theta$; $1 = \sqrt{2} \cos \theta$; $\frac{1}{\sqrt{2}} = \cos \theta$; $\theta = \arccos \frac{1}{\sqrt{2}}$. It is a solution to both equations, this is what we use. The equivalent polar coordinate point is $(\sqrt{2}, \arccos \frac{1}{\sqrt{2}})$. Instead of moving from the origin using horizontal and vertical lines, we take instead the angle, which is the direction, and then moving from the origin a certain distance. Example: Convert the polar point to a rectangular point. $(\sqrt{2}, \pi/4)$. $w\check{a}ks\check{o}cker$ connects the x and y with each other. Be P one point in the plane. Draw perpendiculars from P to the $XOXA$ line and $Yoya$ line. Let PL and PM be the measurements in m , cm or m , etc. Let PL and PM measurements be unit B and one unit respectively. Thus (A, B) are called rectangular Cartesian coordinates of a point P . The lines XOX and $Yoya$ are called X -Axis and Y axis, set by the reference frame in the Cartesian XY plane for which (i) XOX is the X -Axis, (ii) $Yoya$ is the Y axis, and (iii) O is called the origin. If (A, B) are the coordinates of the point P , then it is called the coordinate A or the X coordinate and B is called the coordinate B or the Y coordinate of a point P . In the discussion above, we saw that to determine the coordinate of the point P , we have to measure the lengths of PM and PL . We found that the measurements are respectively a unit and unit B . But with the same distance measurements, the point P can be found at any of the other three positions in the same plane as shown in the adjacent diagram. To determine the exact position of a point in a plane, we have to undetermine the convention for coordinate signs.
