Fit a multiple linear regression model

This chapter will show you how to add two, three and even more numerical explanatory variables to a linear model. In terms of code r, the mounting of a multi-line regression model is simple: just add variables to the model formula specified in the lm command)(in a parallel track model, we had two explanatory variables: a numerical era and a categorical era. Here, we allow both explanatory variables to be numerical. 1,9,1,1,1,1 mount a multiple linear regression model for the total price as a function of the auction duration and the starting price. # mount the model oando the duration and start_pr mod
